One of the main goals of a good and effective structural design is to decrease, as far as possible, the self-weight of structures, because they must carry the service load. This is especially important for reinforced concrete (RC) structures, as the self-weight of the material is substantial. For RC structures it is furthermore important that the whole structure or most of the structural elements are under compression with small eccentricities.

The underlying principle of experimental design is: to extract data from a system in such a way that differences or variation in the data can be unambiguously attributed to the particular process we are investigating. In order to do this we need to know how to maximise the statistical power of an experiment or data collection protocol.
